"The future depends on some graduate student who is deeply suspicious of everything I have said."

Geoffrey Hinton

AIMA Chapter 2

Intelligent Agents

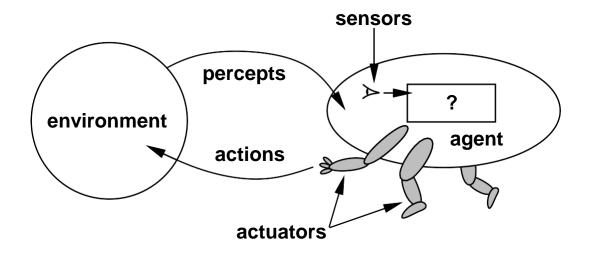

Outline

- ♦ Agents and environments
- **♦** Rationality
- ♦ PEAS (Performance measure, Environment, Actuators, Sensors)
- ♦ Environment types
- ♦ Agent types

Agents and environments

Agents include humans, robots, softbots, thermostats, etc.

An agent can be anything that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators

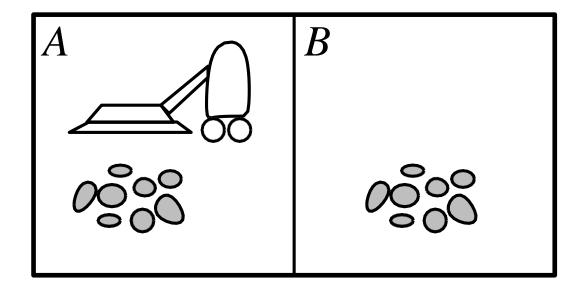

The agent function maps from percept histories to actions:

$$f: \mathbf{P}^* \to \mathbf{A}$$

The agent program runs on the physical architecture to produce f

Vacuum-cleaner world

Percepts: location and contents, e.g., [A, Dirty]

Actions: Left, Right, Suck, NoOp

A vacuum-cleaner agent

What is the right function?

Can it be implemented in a small agent program?

Percept sequence	Action
[A, Clean]	Right
[A, Dirty]	Suck
[B, Clean]	Left
[B, Dirty]	Suck
[A, Clean], [A, Clean]	Right
[A, Clean], [A, Dirty]	Suck
•	•

```
function Reflex-Vacuum-Agent([location,status]) returns an action
if status = Dirty then return Suck
else if location = A then return Right
else if location = B then return Left
```

Rationality

A rational agent is one that **does the right thing**.

Several different notions of the "right thing" -> AI has generally stuck to one notion called **consequentialism**: we evaluate an agent's behavior by its **consequences**.

Recalling Norbert Wiener's warning to ensure that "the purpose put into the machine is the purpose which we really desire", notice that it can be quite hard to formulate a performance measure correctly.

Consider, for example, the vacuum-cleaner agent from the preceding section. We might propose to measure performance by the amount of dirt cleaned up in a single eight-hour shift.

A rational agent can maximize this performance measure by cleaning up the dirt, then dumping it all on the floor, then cleaning it up again, and so on (see "On Superintelligence" book by Bostrom)

Rationality

Fixed performance measure evaluates the environment sequence

- one point per square cleaned up in time T?
- one point per clean square per time step, minus one per move?
- penalize for > k dirty squares?

A rational agent chooses whichever action maximizes the expected value of the performance measure given the percept sequence to date

- Rational != omniscient, percepts may not supply all relevant information
- Rational != clairvoyant, we don't have access to future percepts
- Rational != successful, action outcomes may not be as expected

Rational \Rightarrow exploration, learning, autonomy

Rationality

There are **extreme cases** in which the environment is completely *known a priori* and *completely predictable*. In such cases, the agent **need not perceive or learn**; it simply **acts correctly**.

Such agents are fragile, examples:

- **Dung beetle**: After digging its nest and laying its eggs, it fetches a ball of dung to plug the entrance. If the ball of dung is removed from its grasp en route, the beetle continues its task and pantomimes plugging the nest with the nonexistent dung ball, never noticing that it is missing. **Evolution has built an assumption into the beetle's behavior, and when it is violated, unsuccessful behavior results.**
- Sphex wasp: after digging a burrow, it goes out and sting a caterpillar and drag it to the burrow, enter the burrow again to check all is well, drag the caterpillar inside, and lay its eggs. The caterpillar serves as a food source when the eggs hatch. If an entomologist moves the caterpillar a few inches away while the sphex is doing the check, it will revert to the "drag the caterpillar" step of its plan and will continue the plan without modification, re-checking the burrow, even after dozens of caterpillar-moving interventions. The sphex is unable to learn that its innate plan is failing, and thus will not change it.

The Nature of Environments: PEAS

To design a rational agent, we must specify the task environment

Consider, e.g., the task of designing an automated taxi:

Performance measure

Environment

<u>Actuators</u>

<u>Sensors</u>

PEAS

To design a rational agent, we must specify the task environment

Consider, e.g., the task of designing an automated taxi:

Performance measure: safety, destination, profits, legality, comfort, ...

Environment: US streets/freeways, traffic, pedestrians, weather, . . .

Actuators: steering, accelerator, brake, horn, speaker/display, . . .

Sensors: video, accelerometers, gauges, engine sensors, keyboard, GPS, . . .

"the more restricted the environment, the easier the design problem"

Internet shopping agent

Performance measure:

Environment:

Actuators:

Sensors:

Internet shopping agent

Performance measure: price, quality, appropriateness, efficiency

Environment: current and future WWW sites, vendors, shippers

Actuators: display to user, follow URL, fill in form

<u>Sensors:</u> HTML pages (text, graphics, scripts)

Single-agent	Yes	No	Yes	No

The environment type largely determines the agent design

The hardest case is partially observable, multiagent, nondeterministic, sequential, dynamic, continuous.

The real world falls into this category (of course).

Agents Structure

The job of AI is to design an agent program that **implements the agent function**—the mapping from percepts to actions.

We assume this program will run on some sort of computing device with physical sensors and actuators—we call this the agent architecture:

Agent architecture agent = architecture + program

Most of this course is about designing agent programs.

TABLE-DRIVEN-AGENT

function TABLE-DRIVEN-AGENT(percept) returns an action

persistent: percepts, a sequence, initially empty

table, a table of actions, indexed by percept sequences, initially fully specified

append percept to the end of percepts action ← LOOKUP(percepts, table)
return action

Percept sequence	Action
[A, Clean]	Right
[A, Dirty]	Suck
[B, Clean]	Left
[B, Dirty]	Suck
[A, Clean], [A, Clean]	Right
[A, Clean], [A, Dirty]	Suck
•	•

Figure 2.7 The TABLE-DRIVEN-AGENT program is invoked for each new percept and returns an action each time. It retains the complete percept sequence in memory.

It is instructive to consider why the table-driven approach to agent construction is doomed to failure. Let \mathcal{P} be the set of possible percepts and let T be the lifetime of the agent (the total number of percepts it will receive). The lookup table will contain $\sum_{t=1}^{T} |\mathcal{P}|^t$ entries. Consider the automated taxi: the visual input from a single camera (eight cameras is typical) comes in at the rate of roughly 70 megabytes per second (30 frames per second, 1080×720 pixels with 24 bits of color information). This gives a lookup table with over $10^{600,000,000,000}$ entries for an hour's driving. Even the lookup table for chess—a tiny, well-behaved fragment of the real world—has (it turns out) at least 10^{150} entries. In comparison, the number of atoms in the observable universe is less than 10^{80} . The daunting size of these tables means that (a) no physical agent in this universe will have the space to store the table; (b) the designer would not have time to create the table; and (c) no agent could ever learn all the right table entries from its experience.

TABLE-DRIVEN-AGENT

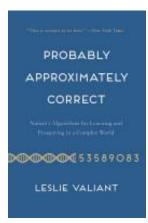

Despite all this, TABLE-DRIVEN-AGENT **does do** what we want, assuming the table is filled in correctly: it implements the desired agent function.

The key challenge for AI is to find out how to write programs that, to the extent possible, produce rational behavior from a smallish program rather than from a vast table.

This also introduce a recurring concept within our course: the *effectiveness-efficiency trade-off*

<u>Nature's Algorithms for Learning and Prospering in a Complex World"</u>, Leslie Valiant (Turing award 2010), 2013.

Agent types

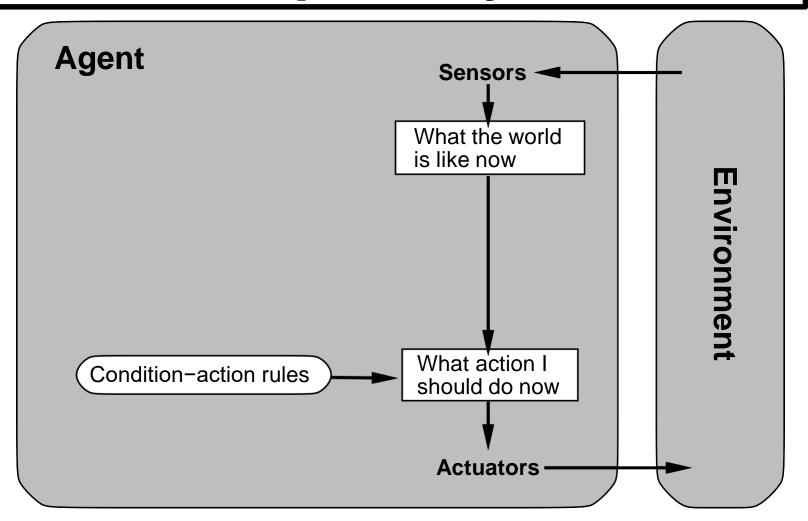

Four basic types in order of increasing generality:

- simple reflex agents
- reflex agents with state
- goal-based agents
- utility-based agents

Each kind of agent program combines particular components in particular ways to generate actions

Simple reflex agents

These agents select actions on the basis of the current percept, ignoring the rest of the percept history

```
function Reflex-Vacuum-Agent([location,status]) returns an action if status = Dirty then return Suck else if location = A then return Right else if location = B then return Left
```

```
function Reflex-Vacuum-Agent([location,status]) returns an action if status = Dirty then return Suck else if location = A then return Right else if location = B then return Left
```

AGENT

Let us now see how we define an agent. Run the next cell to see how Agent is defined in agents module.

```
psource(Agent)
```

The Agent has two methods.

- init (self, program=None): The constructor defines various attributes of the Agent. These include
 - alive: which keeps track of whether the agent is alive or not
 - bump: which tracks if the agent collides with an edge of the environment (for eg, a wall in a park)
 - holding: which is a list containing the Things an agent is holding,
 - performance : which evaluates the performance metrics of the agent
 - program: which is the agent program and maps an agent's percepts to actions in the environment. If no implementation is
 provided, it defaults to asking the user to provide actions for each percept.
- can_grab(self, thing): Is used when an environment contains things that an agent can grab and carry. By default, an agent can
 carry nothing.

```
function Reflex-Vacuum-Agent([location,status]) returns an action if status = Dirty then return Suck else if location = A then return Right else if location = B then return Left
```

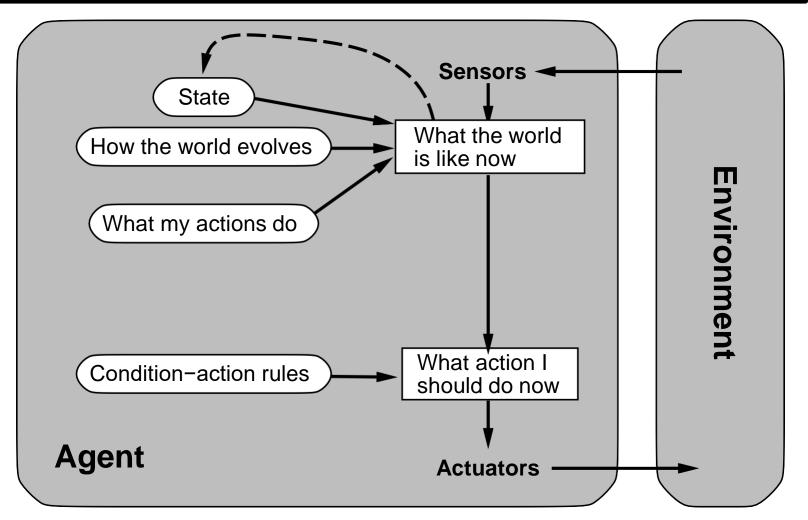

Far better than the **table-driven-agent**:

- The most obvious reduction comes from ignoring the percept history, which cuts down the number of relevant percept sequences from 4^T to just 4.
- A further, small reduction comes from the fact that when the current square is dirty, the action does not depend on the location.

Problem: it only works if decisions can be made on just the current percept and the env. is fully observable. -> ex. vacuum agent without location sensor.

Model-based agents

The most effective way to handle partial observability is for the agent to keep track of the part of the world «it can't see now».

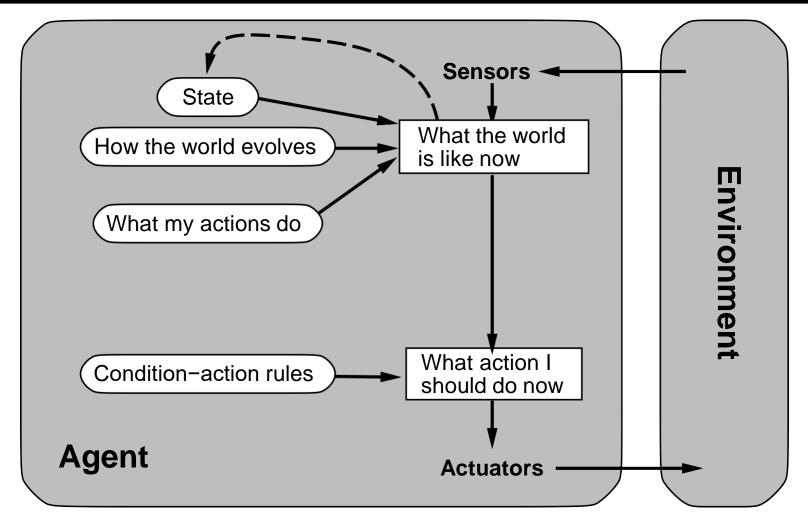

Figure 2.12 A model-based reflex agent. It keeps track of the current state of the world, using an internal model. It then chooses an action in the same way as the reflex agent.

The details of **how models and states are represented vary widely** depending on the type of environment and the particular technology used in the agent design.

Model-based agents

Goal-based agents Sensors -State What the world How the world evolves is like now Environment What it will be like What my actions do if I do action A What action I Goals should do now **Agent Actuators**

Sometimes goal-based action selection is straightforward—for example, when goal satisfaction results immediately from a single action. Sometimes it will be more tricky. **Search** and **planning** are the subfields of AI devoted to finding action sequences that achieve the agent's goals.

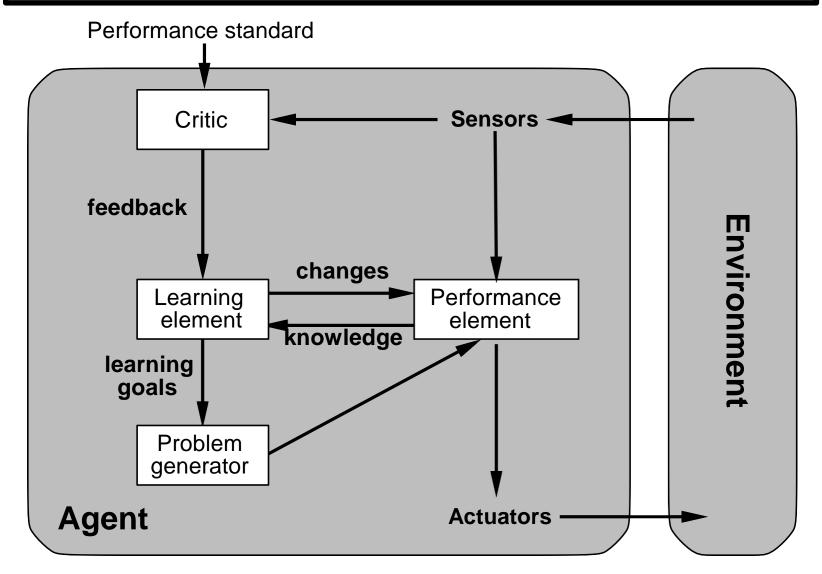

Utility-based agents Sensors -State What the world How the world evolves is like now Environment What it will be like What my actions do if I do action A How happy I will be Utility in such a state What action I should do now Agent **Actuators**

A **performance measure** assigns a score to any given sequence of environment states, so it can easily distinguish between more and less desirable ways of getting to the taxi's destination. An agent's **utility function** is essentially an internalization of the performance measure.

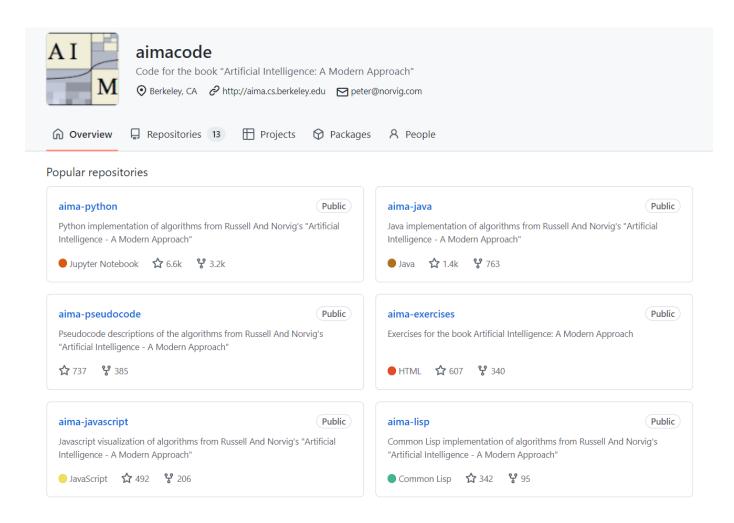

Learning agents

The most important distinction is between the **learning element**, which is responsible for making improvements, and the **performance element**, which is responsible for selecting external actions.

The Vacuum World

https://github.com/aimacode/aimapython/blob/master/vacuum world.ipynb

Summary

Agents interact with environments through actuators and sensors

The agent function describes what the agent does in all circumstances

The performance measure evaluates the environment sequence

A perfectly rational agent maximizes expected performance

Agent programs implement (some) agent functions

PEAS descriptions define task environments

Environments are categorized along several dimensions:

observable? deterministic? episodic? static? discrete? single-agent?

Several basic agent architectures exist:

reflex, reflex with state, goal-based, utility-based, ... other agent architectures are possible!
